

Abstract

A decorative sock includes a three-dimensional ornament which relates to two-dimensional indicia on the body of the sock. The ornament may take many forms, including an animal head, cellular phone, star and the like, that is attached to the sock at or near its opening where the foot is typically inserted into the sock. Use of a stuffed skin to form an ornament provides more appeal and versatility than previously known prior art socks, since the ornament can assume complex shapes. Further, the various relationships between the three-dimensional ornaments and two-dimensional indicia, as embodied in this invention, provide more appeal and encourage the stimulation and education of young children with new ideas and concepts.
